

PJM Markets 201

Generation Contingency Analysis

PJM State & Member Training Dept.

Student will be able to:

- Describe the processes and tools associated with performing contingency analysis
 - Identify the procedure for re-dispatching generation to alleviate an overloaded monitored transmission line caused by a contingency

Operational Limits

- **Thermal Limits** - Thermal limits are due to the heat dissipation capability of power system equipment
- **Voltage Limits** - Utility and customer equipment is designed to operate at a certain supply voltage (or a small range around an ideal voltage)
- **Stability Limits** - Refers to the power system maintaining a state of equilibrium

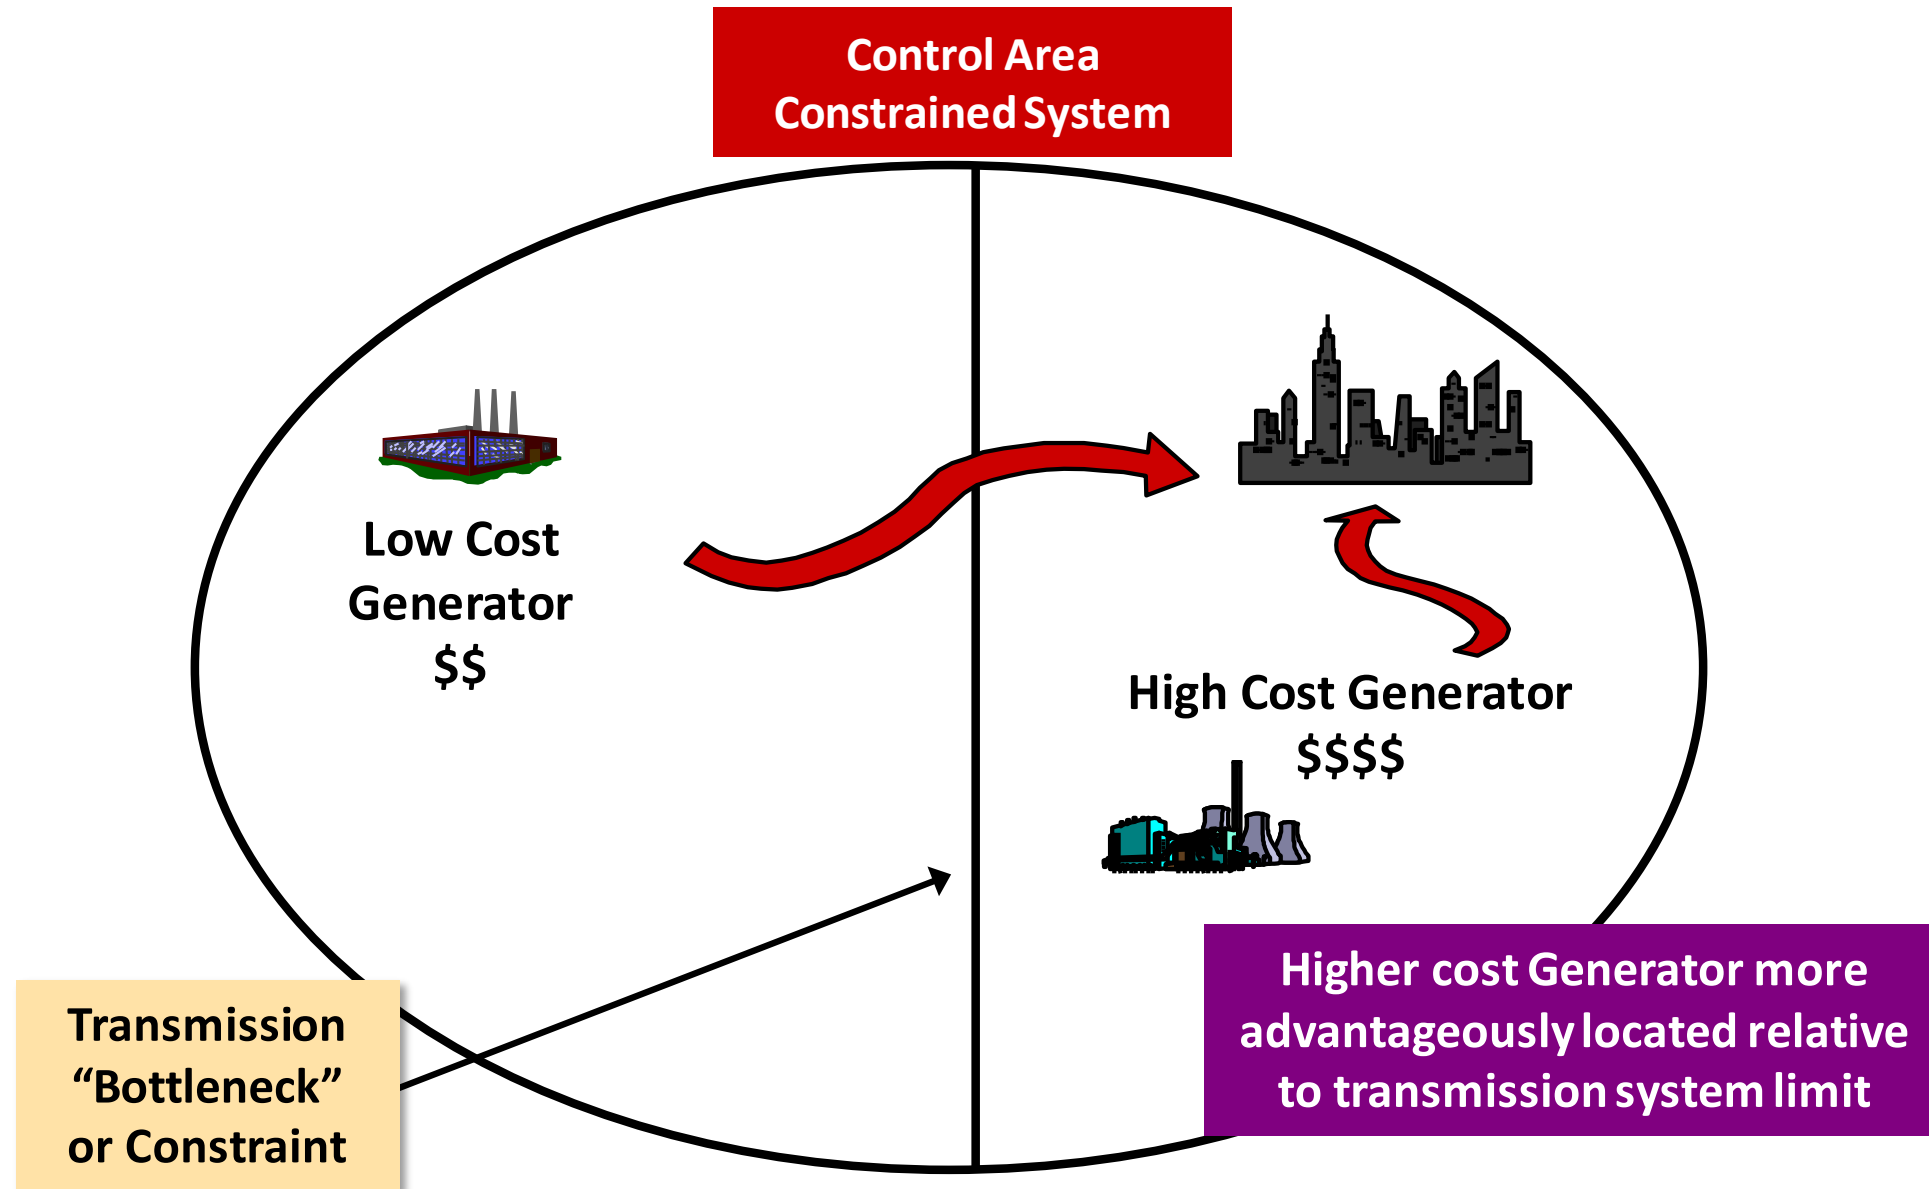

Control Actions

- There are three basic types of actions that can be performed to control the flow of power on the electric system:
 - ❶ System Reconfiguration
 - ❷ Transaction Curtailments
 - ❸ Redispatch Generation

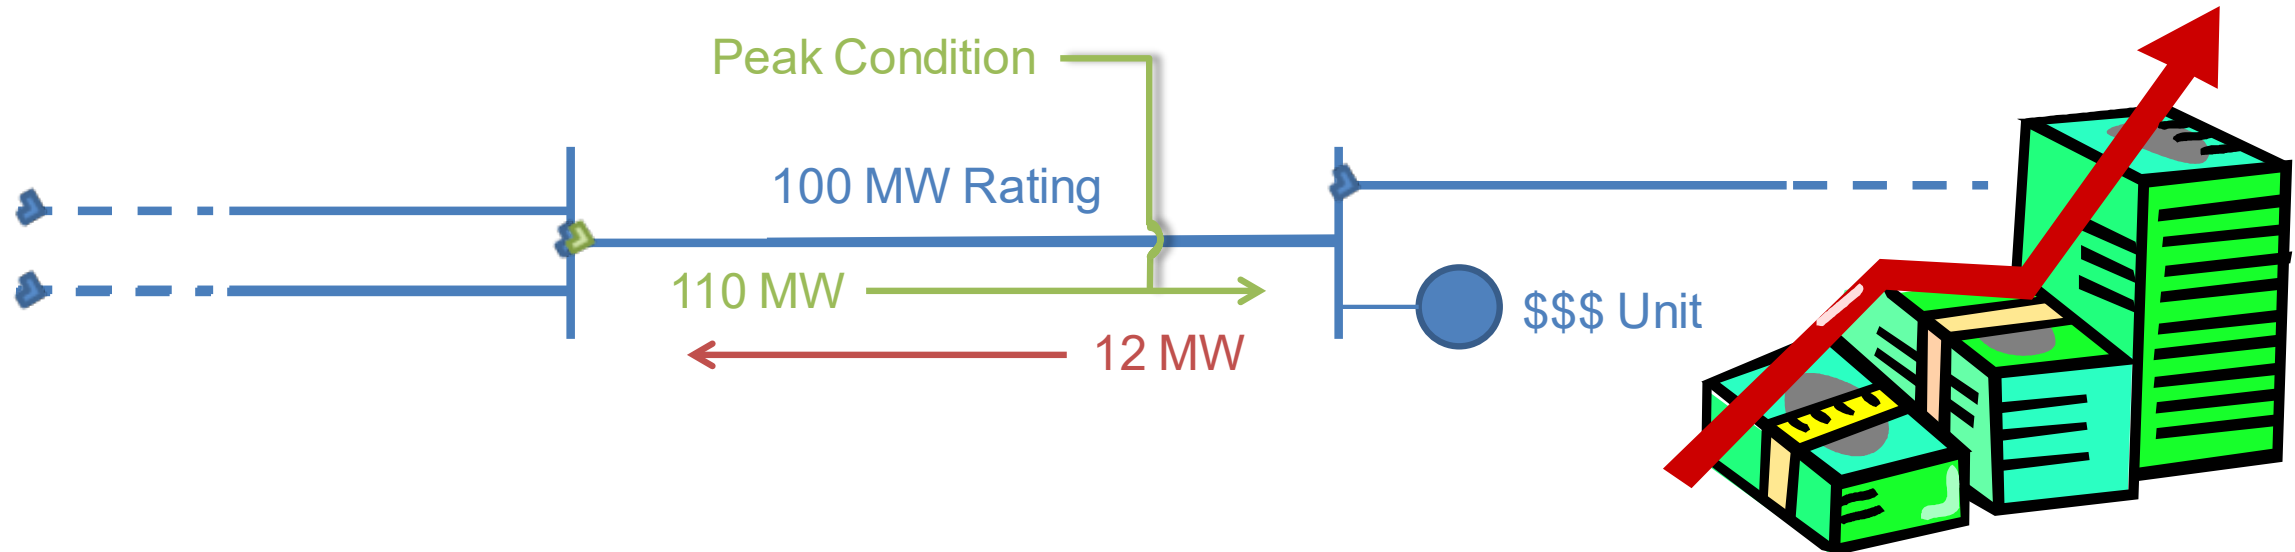

Security Constrained Re-Dispatch

When Constraints Occur...

- Delivery limitations prevent use of “next least-cost generator”
- Higher-cost generator closer to load must be used to meet demand
- Cost expressed as “security constrained redispatch cost”

Constraints & Marginal Units

- There will always be at least one marginal unit
 - System Energy Unit
- There will be an additional marginal unit for each binding constraint
- It is possible, and in fact likely, that there will be multiple marginal units for a given time interval

Contingency Analysis

- “What if” scenario simulator that evaluates, provides and prioritizes the impacts on an electric power system when problems occur.
 - A contingency is a provision for an unforeseen event or circumstance
 - Loss or failure of a **small** part of the power system (e.g. a transmission line)
 - Loss or failure of individual equipment such as a generator or transformer
- A computer application that uses a simulated model of the power system
 - Evaluates the effects of an outage event
 - Calculates any overloads that may result
- This is referred to as maintaining system security

Contingency Analysis

- Contingency Analysis is essentially a "preview" analysis tool
 - It simulates and quantifies the results of problems that could occur in the power system in the immediate future
- Contingency Analysis is used as a study tool for the off-line analysis of contingency events, and as an on-line tool to show operators what would be the effects of future outages
 - This allows operators to be better prepared to react to outages by using pre-planned recovery scenarios.

How Contingency Analysis Works

- Executes a power flow analysis for each potential problem that is defined on a contingency list
 - A contingency list contains each of the elements that will be removed from the network model, one by one, to test the effects for possible overloads of the remaining elements
 - The failure or outage of each element in the contingency list is simulated in the network model by removing that element
 - The resulting network model is solved to calculate the resulting power flows, voltages, and currents for the remaining elements of the model

Generation Re-dispatch

For Contingency Analysis

PJM Real Time Contingency Operations

- Review available controlling actions and the distribution factor (DFax) effect on the overloaded facility.
 - Consider whether there are sufficient resources available to control transmission facilities within acceptable limits.
- Initiate off-cost if reasonable controlling actions are available
- SCED works best when the impacts are 5% or greater but can still be utilized when only lower DFax values exist

PJM Real Time Contingency Operations

- Once off-cost is initiated, RT-SCED will redispatch generation based on its dollar per MW effect, considering all on-line flexible units with an impact of ~1% or greater
 - This percentage may be adjusted on a case by case basis
- Initiate a Post Contingency Local Load Relief Warning/Action if post-contingency flows exceed designated ratings and insufficient resources are available to control the overloaded facilities

Real Time Contingency Operations

- During Constrained Operations, resources will be redispatched cost-effectively based on their bid parameters
- **Cost-effective redispatch (\$/MW Effect) = (Current Dispatch Rate – Unit Bid)/Unit Shift Factor**
 - SMP and Marginal Cost of Unit values are the result of optimization
- Units with lowest \$/MW effect are used to re-dispatched when the system is constrained

| DFAX sign | \$/MW Effect for Raising Output | \$/MW Effect for Lowering Output |
|----------------------------|---------------------------------|----------------------------------|
| Negative DFAX = Raise Help | Choose Lowest | Choose Highest |
| Positive DFAX = Lower Help | Choose Highest | Choose Lowest |

- Unit parameters are taken into account and honored (i.e. eco min, eco max, min run time, etc.)

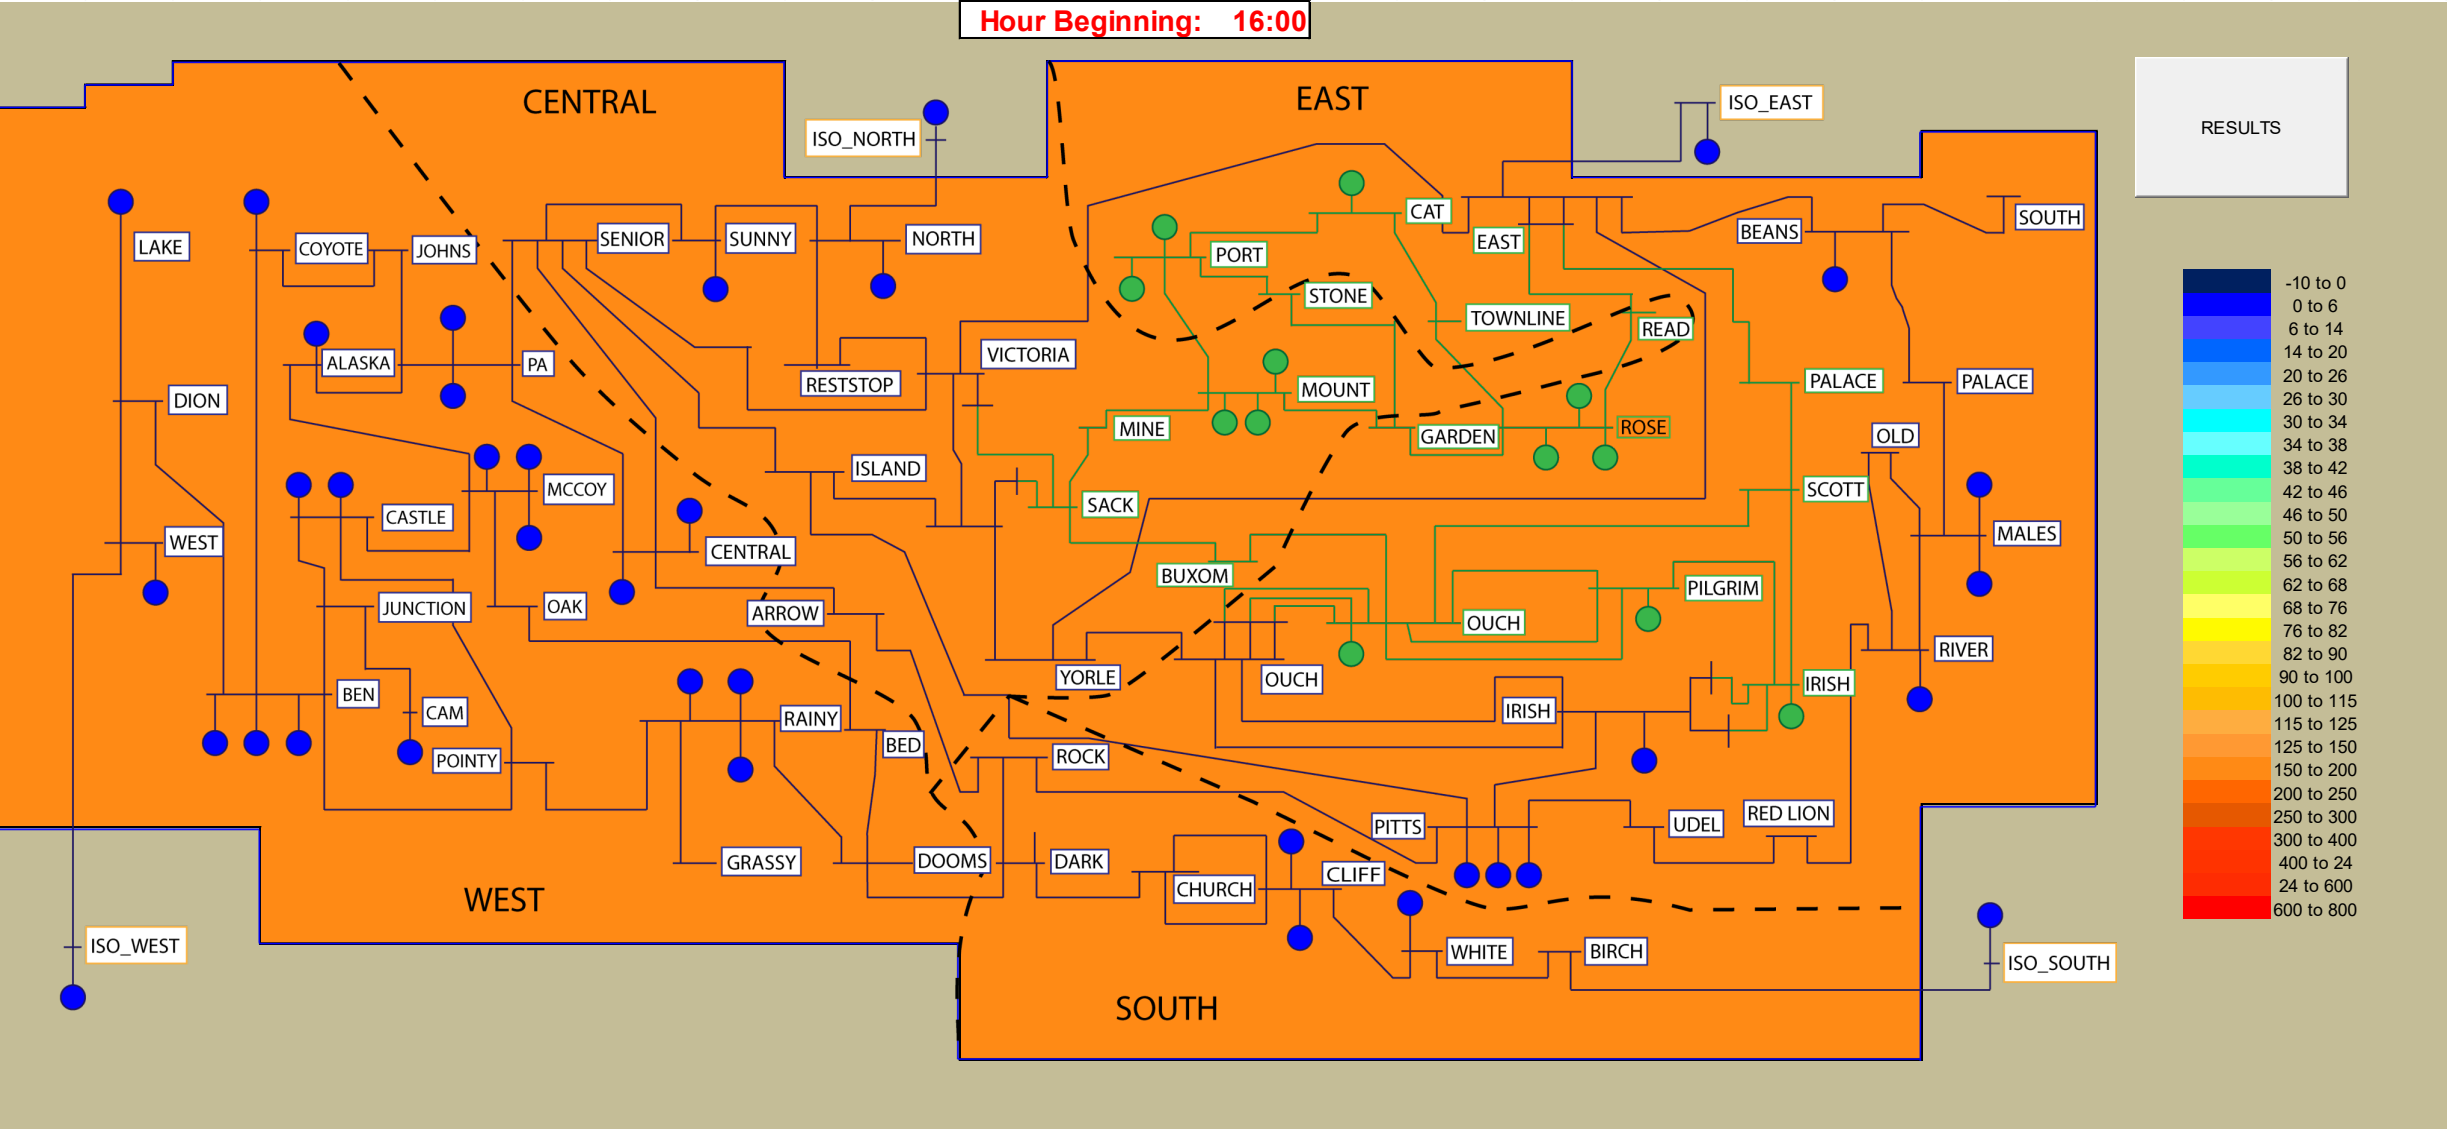

Generation Shift Factors

Generation Shift Factors

- The change (or sensitivity) of active power flow in a reference direction on a transmission line with respect to a change in injection at the generator bus and a corresponding change in withdrawal at the reference bus
 - Calculated with a DC Power Flow
- Shift Factors change when:
 - Transmission topology changes
 - Line impedance changes
- Also known as Generation DFax

Contingency Analysis Demo

Base Case – LMP Contour Map

Constraint Re-dispatch

- Units with lowest \$/MW effect are re-dispatched when system is constrained
 - Iterative approach: \$/MW recalculated as MW change

Constraint Re-dispatch

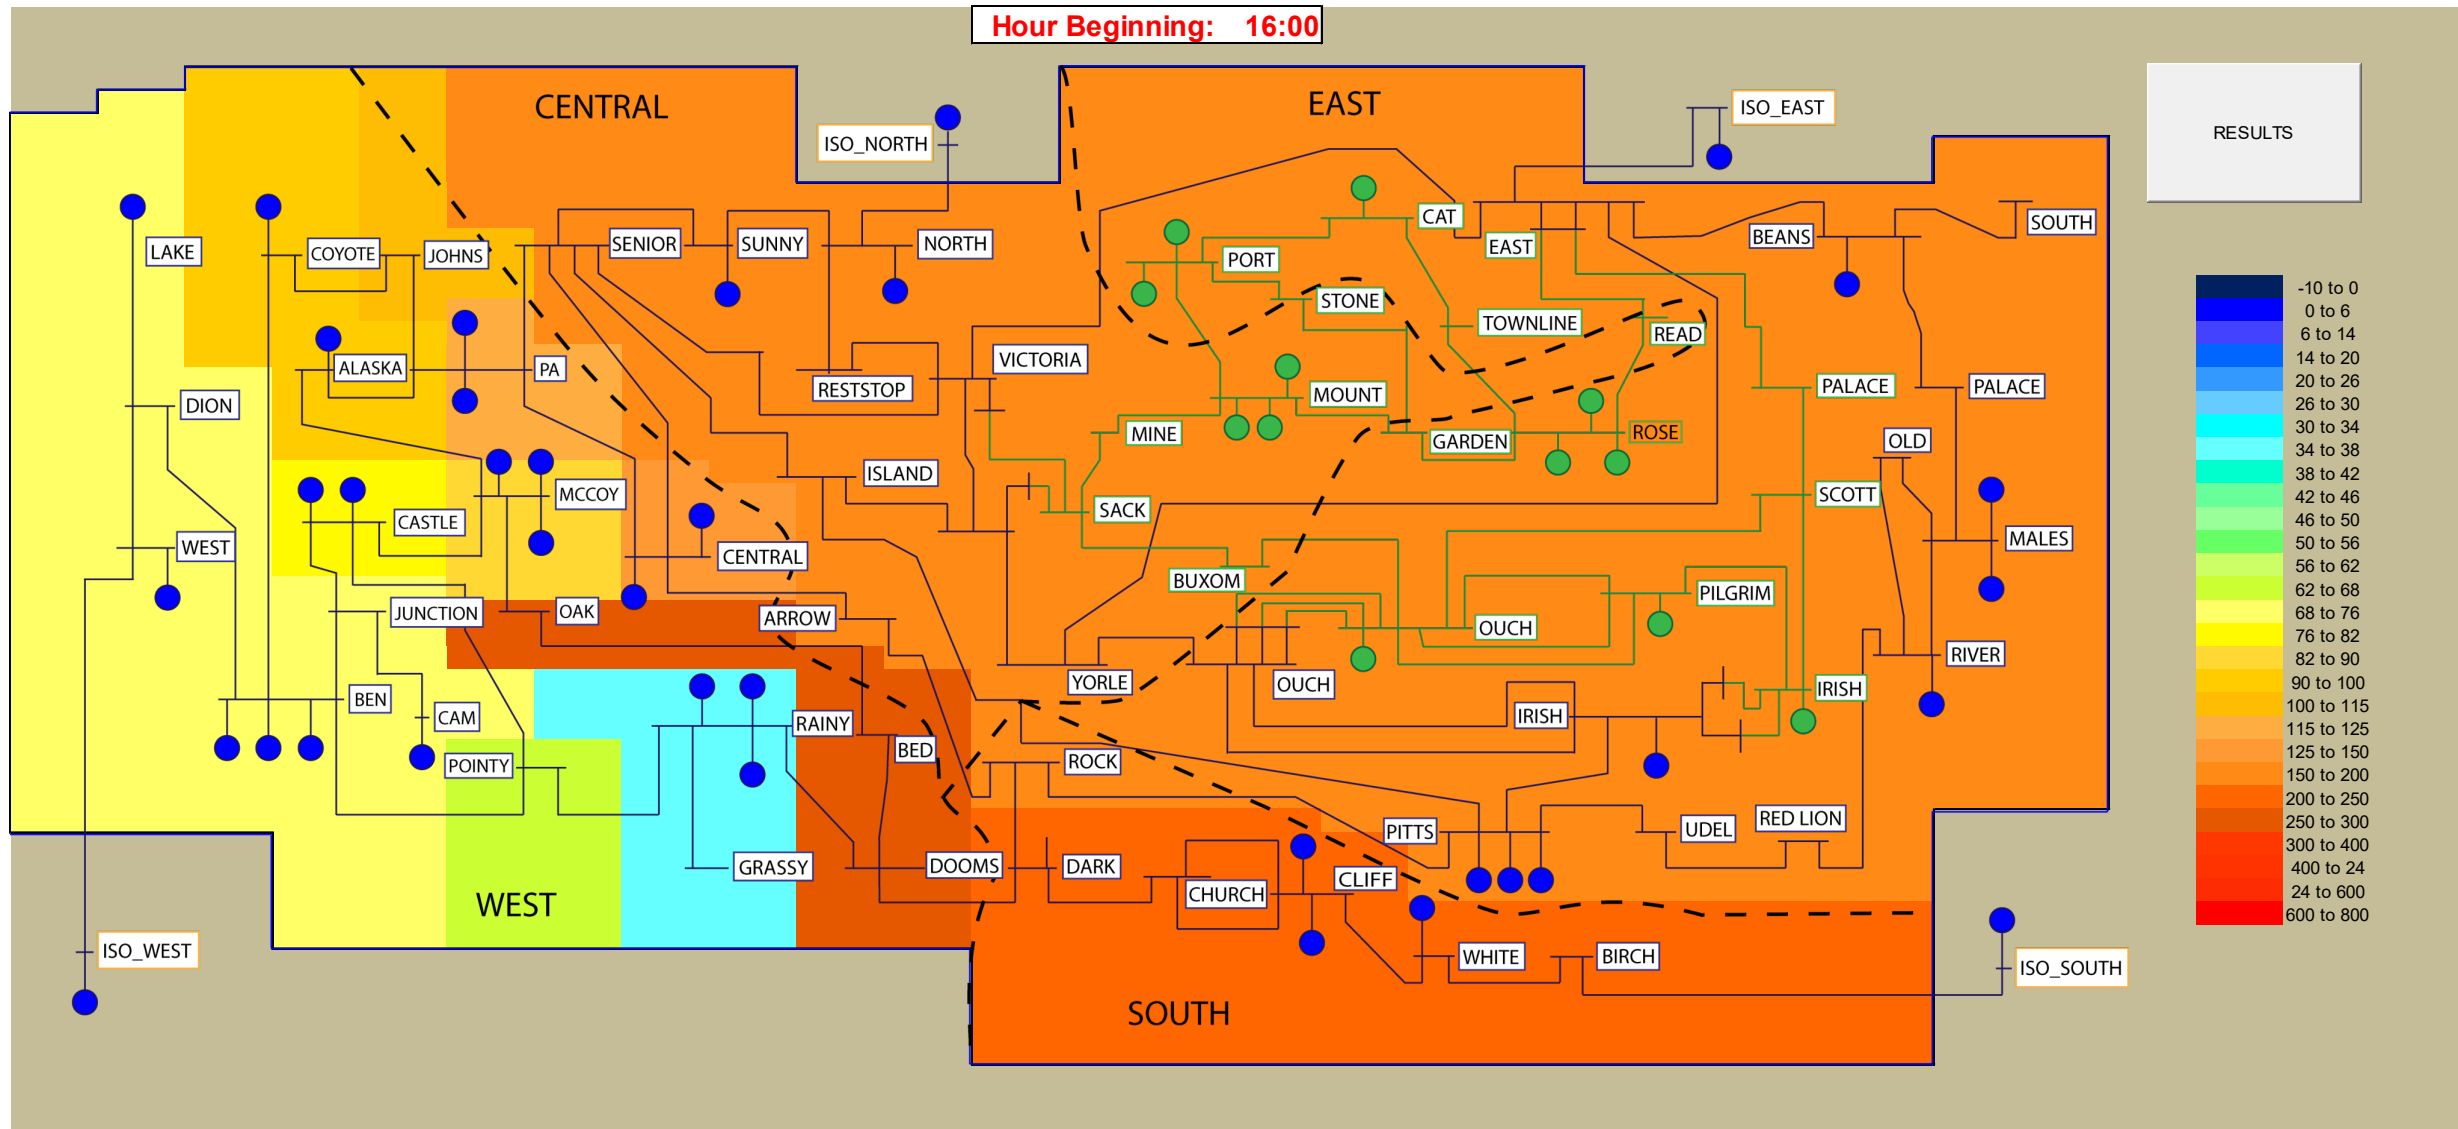

- Units with positive Dfax/added flow were decreased
- Units with negative Dfax/removed flow were increased
- This was a peak load case and units with a negative DFax and low \$/MW could not be increased since they were at economic max
 - Example – Cliff 1 and 2 at economic max
- Other units with higher \$/MW were needed to increase
 - Ouch CC was needed to increase

\$/MW Effect Calculation Used in Real-Time Operations

| | | Base Case | | | Constrained Case | | | | | |

| Units with positive DFAX are needed to decrease output | | | | | | | | | | |
| Units with negative DFAX are needed to increase output | | | | | | | | | | |
| $\$/\text{MW Effect} = (\text{Current Dispatch Rate} - \text{Unit Bid}) / \text{Unit Shift Factor}$ | | | | | | | | | | |
| Current Dispatch Rate = \$169.99/MWh | | | | | | | | | | |

Congestion Price Demo

Constrained Case – LMP Contour Map

Post Contingency Dispatch Summary

- 9 units were re-dispatched to control the constraint
 - Marginal unit setting System Marginal Price was increased
 - 8 other units were adjusted
- The highest cost unit that was decreased is the marginal unit controlling the constraint
 - Rainy 3

Units Re-dispatched to Control Constraint

| UnitName | unitType | Zone | Redispatched MW Disptch | Base Case MW Disptch | Delta | Bid\$@Disp |
|---------------|----------|---------|----------------------------|-------------------------|--------|------------|
| MOUNT 3 F | Steam | CENTRAL | 451.4 | 250 | 201.4 | 33.06 |
| MOUNT 4 F | Steam | CENTRAL | 430 | 0 | 430 | 58.18 |
| PILGRIM CC1 F | Steam | EAST | 496.5 | 451.8 | 44.7 | 170 |

| OUCH CC | Steam | EAST | 355 | 0 | 355 | 165 |
| RAINY 2 | Steam | WEST | 0 | 530 | -530 | 25.51 |
| RAINY 3 | Steam | WEST | 308.5 | 504 | -195.5 | 34.53 |
| MCCOY 3 F | Steam | WEST | 0 | 460 | -460 | 25.9 |
| LAKE 1 F | Steam | WEST | 400 | 525 | -125 | 27.91 |

Shadow Price

- Rainy – Dooms 500 KV line rating is 1990 MVA
- Calculate shadow price for Rainy – Dooms 500 KV line
 - Re-dispatch the system using a DC power flow with Rainy – Dooms rating at 1991 MW
 - Calculate the new total system production cost and subtract that from the post contingency case production cost
 - The difference in production cost is the shadow price

Shadow Price

- Post contingency case production cost = \$11,081,725.40
- Production cost with 1 more MW across the Rainy – Dooms 500 KV line = \$11,081,422.58
- With 1 more MW across the Rainy – Dooms 500 KV line the saving in Production cost is **-\$302.82, which is the shadow price**
 - Pilgrim CC1 decreased by 2.25MW
 - Rainy 3 increased by 2.25 MW

Class Problem – Calculate Change in Rainy – Dooms Line Flow

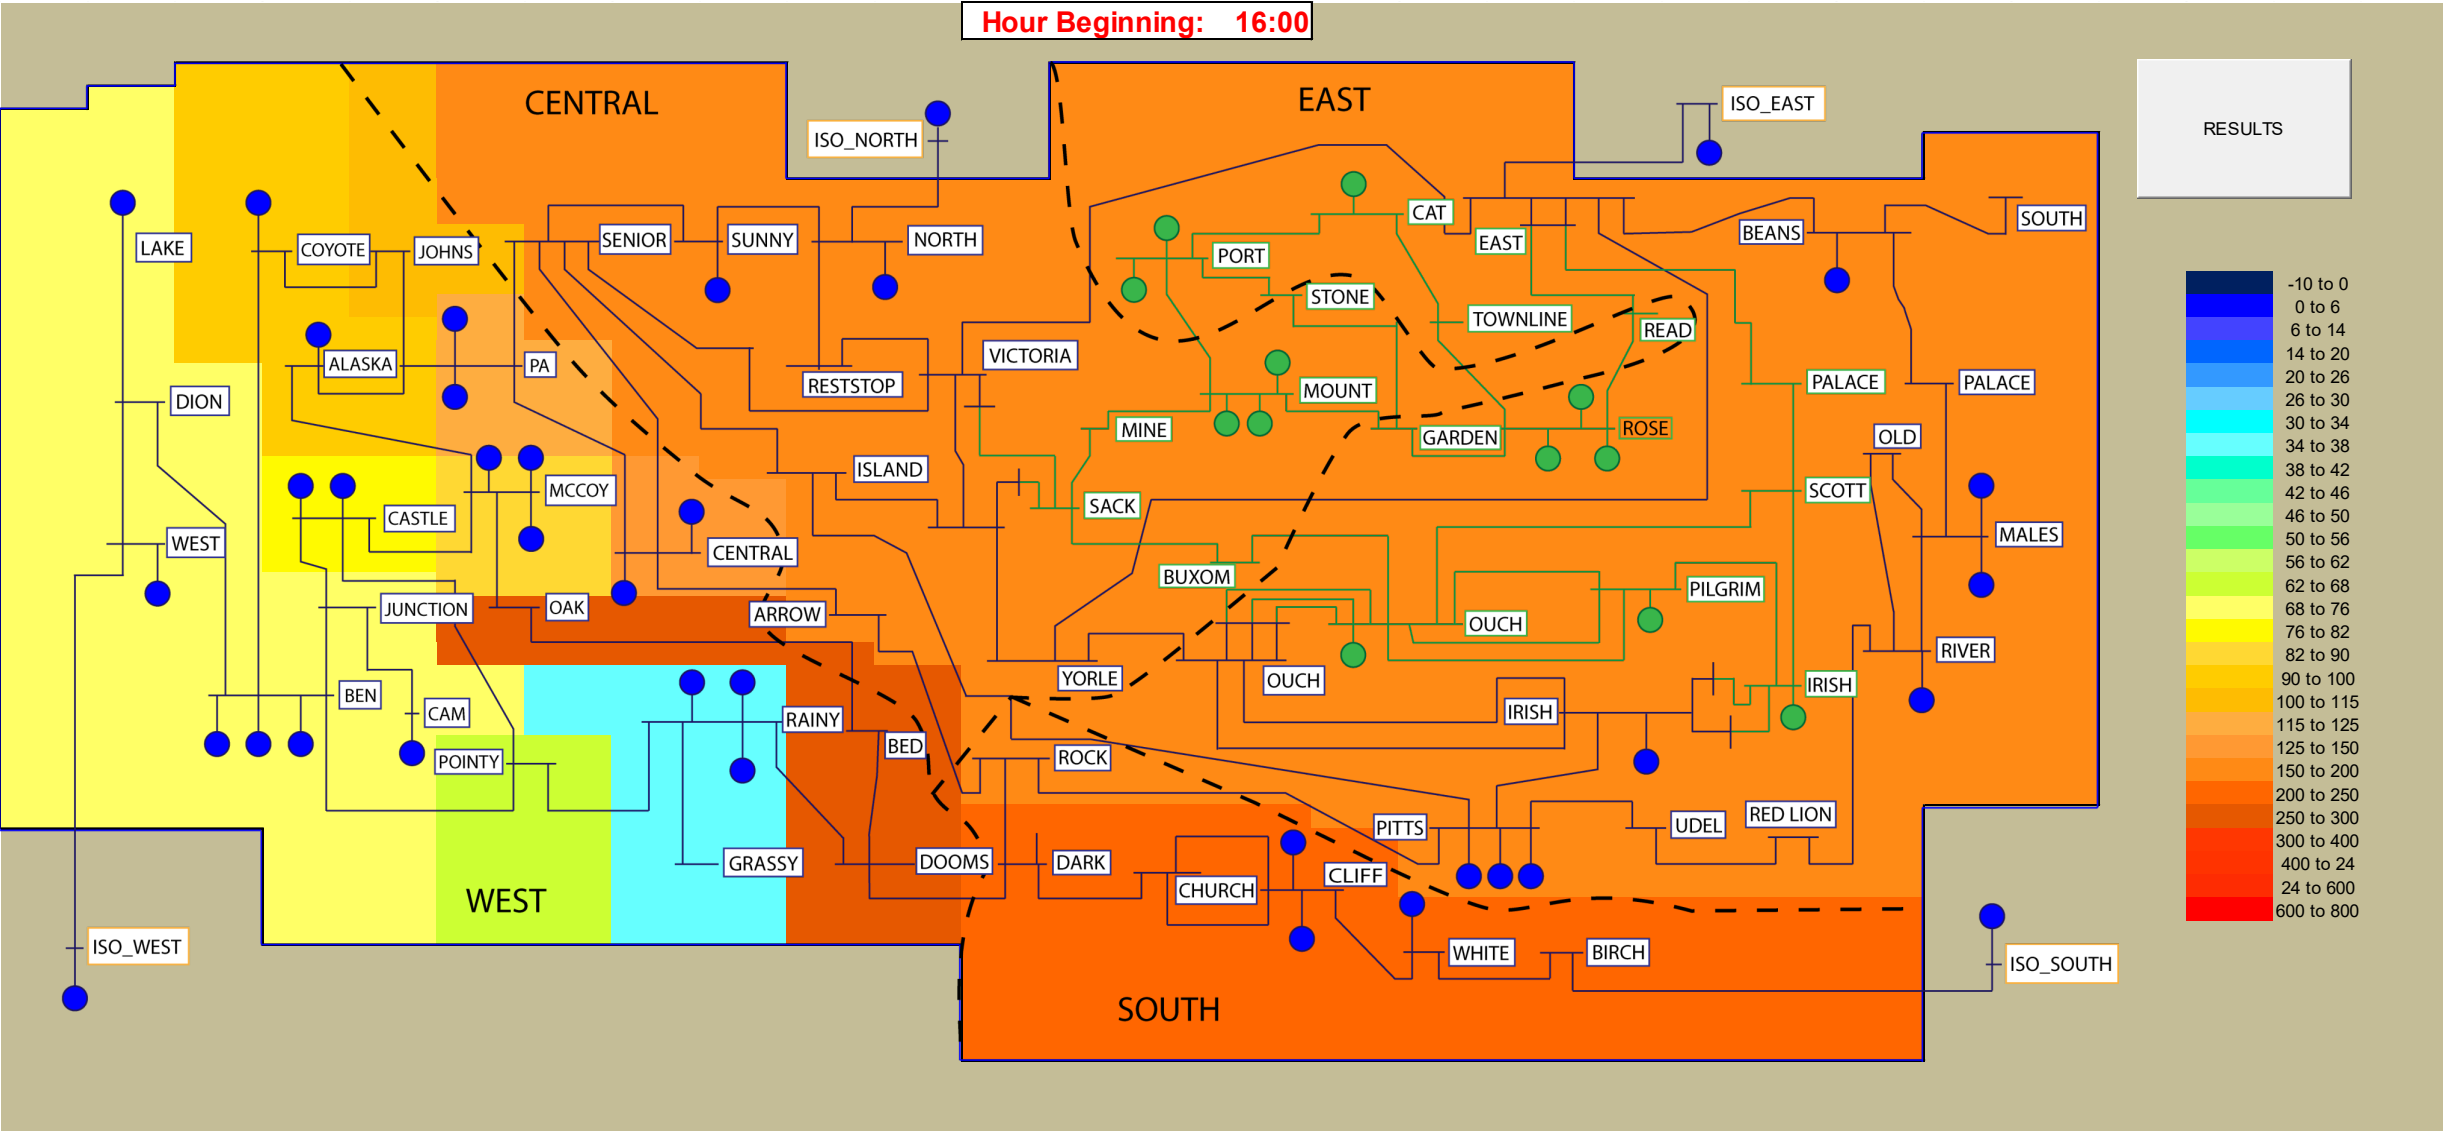

- Pilgrim CC1 decreased by 2.25MW
 - DFAX (Rainy – Dooms) = -0.0097
- Rainy 3 increased by 2.25 MW
 - DFAX (Rainy – Dooms) = 0.4344

Congestion Component of LMP

$$\text{Congestion Component} = \text{Shadow Price} * \text{DFAX}$$
